rc frames under earthquake loading The assessment of the respoonse of reinforced concrete frames to earthquakes is essential in many parts of the world. Therefore, the design and assessment of the structures which are likely to be subjected to such actions require the application of non-linear analysis using finite element techniques of different degrees of complexity.

BEHAVIOR OF AAC INFILLED RC FRAME UNDER LATERAL LOADING

There were RC frame buildings with shear walls among the damaged RC buildings in Van. Shear wall has a significant role in carrying earthquake loads however they should be designed and constructed properly. Many RC frame buildings with shear walls were also damaged in Van since shear walls were not designed properly to a seismic code requirements.

This study employed 8-storey RC frames with setback as shown in Figure 3. Frame IS1 was designed for gravity load only and Frame IS2 was designed to resist horizontal earthquake with PGA equals to 0.2g and soil class B according to Eurocode 8 [3]. The detail information on the design of these frames can be found in Hartzigeogiou and Liliou 's [9].

Reinforced Concrete (RC) and Steel buildings under the action of lateral loads, especially during earthquakes. Since most buildings built in India are made of RC, the dominant set of examples used is of RC buildings. But, with no loss of generality, the broad concepts discussed in this document are valid for both RC and Steel buildings.

Some Concepts in Earthquake Behaviour of Buildings

A series of multistory RC frames were designed for gravity loads only (1.4D.L+1.7L.L) without considering the seismic loads as typically found in most seismic prone countries before the introduction of adequate seismic design code provisions. All frame models have a constant 3m story height except the ground story is 4m (Fig.2).
